strument asked the respondent to state "how old were you when you first "came out" about being into S/M?" The mean age was 22.7 years which does not differ from the Breslow mean, t(69) = 0.52, p > 0.10.

Breslow subjects were required to report the "number of different sadomasochistic encounters during the previous 12 months." Our parallel question asked "how often have you had an S/M scene?" but the time period was the past 6 months. The means are 53 and 66, respectively. Though these means are obviously not directly comparable, we note that the difference is nonsignificant, t(60) = 0.06, p > 0.10, as a preliminary to a more logical, though artificial, test of this variable. Assume that our sample mean for a full year would have been twice the 6-month mean and the variance would remain the same, certainly not inconceivable events. This assumed mean of 132 is significantly greater than the Breslow sample mean, t(60 = 3.76, p < 0.001.

An hypothesis that explains this substantial intersample discrepancy in reported frequency of S/M contacts concerns the intersample differences in marital status and educational level. If married women and those with lower educational attainment tend to have fewer S/M contacts these tendencies could account for the intersample discrepancy, since these two groups are overrepresented in the Breslow sample. These conjectures are reasonable in light of the surveys that consistently show that unmarried women and those with more education tend to be more active sexually.

In fact, this turns out to be the case. As Table III indicates, college-educated women had 50% more S/M contacts on the average than those with no more than a high school education. The never-married women had 70% more S/M contacts than the married women. The differences in Table III are actually not statistically significant, F(2, 31) = 0.81, p = 0.43, and F(2, 31) = 1.54, p = 0.23, respectively but statistical significance is not a requisite for these variables to have influenced the frequency of S/M contacts. It is the absolute differences that are meaningful.

Table III. Relationships Between the Frequency of S/M Contacts and Educational Level and Marital Status in the Levitt et al. Sample

al. Levitt et al.	Breslow et al.	Activity

The Breslow subjects were asked to estimate how frequently they felt "dirty" or "perverted" because of their sexual interests, on a 5-point scale ranging from *never* to *always*. Our subjects were required to respond to the true-false statement, "I wish I were not into S/M." Again, these stimuli appear parallel though perhaps not directly comparable. We combined the five categories of the Breslow question into a dichotomy in two ways: pooling *sometimes* with *never*, and *sometimes* with *always*. The former yielded 15.4% who felt dirty or perverted, the latter, 7.7%. Of our subjects, 12.5% responded "true" to the item asking if they wished they were not into S/M. Comparisons with the rearrangements of the Breslow item yielded $\chi^2(1) = 0.00$ and 0.08, p > 0.70, respectively.

Breslow listed the percentages of subjects reporting that they enjoyed any of 21 S/M activities. We asked our subjects to tell us which ones of 57 activities they had experienced and enjoyed. A comparison of the 13 behaviors that are common to the two investigations is shown in Table IV.

The point of Table IV is the similarity of interests in the two samples rather than isolated differences which could easily be a consequence of sampling error. Both samples manifested clear preferences for bondage, spanking (the traditional bondage and discipline duo), oral sex, and the master-slave game, activities that go together. Neither sample expressed much interest in coprophilia, urolagnia, enemas, or transvestism, the latter not unexpected in a female sample. Over the 13 activities, the rank order

DISCUSSION

is reasonably accurate, the following additional inferences concerning nonprostitute women in the S/M subculture are warranted. to study. On the assumption that our identification of a prostitute subsample is that women are indeed found in the S/M subculture in sufficient numbers an inference that is clearly feasible from the joint impact of the two samples need to advertise to find partners. Despite the methodological differences, as the differences in marital status, may be due in part to the discrepancy in in income and frequency of S/M contacts. However, these differences, as well sample. We have proposed hypotheses to explain the intersample differences partners and hence to be more active sexually than persons who apparently port group with any regularity would surely have greater opportunity to find methodology. For example, individuals who attend meetings of an S/M supmethodology and the need to identify a probable prostitute subsample in our Accurate comparison of the two samples is hampered by differences in
